

Question 1

Every piece of data in this HRMS flows toward one output. What is that output, and why does everything else revolve around it?

Ans- Every aspect of this process comes down to the one thing: the worker gets paid the correct amount of money at the correct time. The system isn't for producing the payslip, or the processing of the data. Those things are just functions within the process.

At the heart of it is the worker gets their money at the right time and the right amount.

The system in its totality, viewed that way, has several steps in sequence of events: the first steps being the onboarding, set-up of the profile and records .Who is this worker, and what are the applicable rules for that worker? Then capturing attendance and overtime, in order to understand what has occurred. Then calculating by way of salary calculation, attendance calculation, and deductions. Producing the payslip where the worker is due certain money.

And then actually making the payment to the worker.

Everything comes down to the worker getting paid the right amount of money at the right time.

Subsequent steps are not checking if earlier steps are right, they're using the inputs. So if the attendance is wrong, overtime is wrong, salaries are stale, deductions are wrong, it won't be corrected.

It's going to be carrying across, impacting the amount of money the worker is going to receive, so everything in the process is extremely important in as much as it may help, or may hurt, achieving the fact that the worker is going to get the right amount of money at the right time.

The worker gets their pay, everything in this system is connected to the workers pay. The focus of our effort is on delivering the workers pay accurately and on time. How is it now

Question 2

Who is the most vulnerable person in this system, and what does a system failure mean for them specifically not in the abstract, but this month?

Ans-The worker is the vulnerable person in this system especially the worker who gets paid daily or depends on overtime. The workers earnings for the month are directly tied to attendance and overtime being recorded correctly. The worker does not use the HR system much but they have the least idea of what is going on in the system. They also have the ability to find mistakes before they cause problems and the least amount of money to fall back on when things go wrong.

For the people in HR or finance a mistake with payroll usually means they have to do some work. They have to fix the mistake report it to someone or deal with a delay. For the worker the same mistake can cause big problems right away. If they do not get paid enough they might not be able to pay rent buy food pay for school or make a loan payment that month. If they get paid late it can be just as bad as getting paid the amount because the worker needs to get paid on time to take care of their family. If something is deducted from their pay by mistake or if they do not get paid for overtime it can seem like they are being treated unfairly even if it was a mistake.

The worker is the vulnerable person in this system because they feel the full effect of payroll mistakes but they have no control, over what happens. The worker is affected by payroll mistakes. The worker has to deal with the problems that payroll mistakes cause but the worker cannot do anything to prevent payroll mistakes from happening.

Question 3

Trace what happens when a site manager enters the wrong overtime hours for a worker. Where does that error travel, who should catch it, and who actually catches it?

Ans- If a site manager puts in the overtime hours for a worker the mistake starts at the Overtime stage but does not stay there. It moves through the payroll process. Can lead to a wrong payment unless there are clear checks to stop it.

A likely flow is:

1. Overtime entry – the site manager puts in OT hours for a worker (for example 12 hours instead of 2 or OT entered for the wrong worker/date).
2. Attendance – those OT hours are added to attendance data to find payable hours for the cycle.
3. Salary Config / payroll rules – the OT hours are multiplied by the worker's rate so the original mistake is now a money error.
4. Deductions / pay computation – gross pay is calculated from the incorrect payable hours then deductions are applied, making the final net pay wrong.
5. Payslip Generation – the system makes a payslip showing the OT amount.
6. Payout – if nothing stops the flow the wrong amount is paid to the worker.

Who should catch it?

Ideally the error should be caught at 3 levels, not just one:

At data entry: the system should check for OT values example OT beyond allowed limits OT on absent days

At approval/review: a supervisor or payroll reviewer should see OT spikes before payroll is finalized.

At payroll calculation review: exception reports should flag workers whose OT or total pay sharply deviates from patterns.

Who actually catches it?

In systems often nobody catches it until the worker sees the payslip or gets the wrong payout. That is why this is a high-risk path. The error can move through every step because each step assumes the previous data is correct. If there are no validation rules, approval checks or exception reports the system will convert one mistake into a wrong payslip and then a wrong payment.

So the key testing implication is this: the overtime path needs protection at the point of entry during payroll review and, before payout because later stages are not fixing the error. They are making it worse.
